How do babies with super-black names fare?
By Steven D. Levitt and Stephen J. Dubner

Which is more dangerous: a gun or a swimming pool? How much does campaign spending really matter? What truly made crime fall in the 1990s? These are the sort of questions raised—and answered—in the new book *Freakonomics: A Rogue Economist Explores the Hidden Side of Everything*. In today's excerpt, the first of two, authors Steven D. Levitt and Stephen J. Dubner explore the impact of a child's first name, particularly a distinctively black name. Tomorrow's excerpt shows how names work their way down the socioeconomic ladder.

It has been well established that we live in an age of obsessive, even competitive, parenting. The typical parent is led to believe that her every move will greatly influence her child's future accomplishments. This belief expresses itself in the first official act a parent commits: giving the baby a name. Many parents seem to think that a child will not prosper unless it is hitched to the right one; names are seen to carry great aesthetic and even predictive powers.

This might explain why, in 1958, a New York City father named Robert Lane decided to call his baby son Winner. The Lanes, who lived in a housing project in Harlem, already had several children, each with a fairly typical name. But this boy—well, Robert Lane apparently had a special feeling about him. Winner Lane: How could he fail with a name like that? Three years later, the Lanes had another baby boy, their seventh and last child. For reasons that no one can quite pin down today, Robert decided to name this boy Loser. Robert wasn't unhappy about the new baby; he just seemed to get a kick out of the name's bookend effect. First a Winner, now a Loser. But if Winner Lane could hardly be expected to fail, could Loser Lane possibly succeed?

Loser Lane did in fact succeed. He went to prep school on a scholarship, graduated from Lafayette College in Pennsylvania, and joined the New York Police Department, where he made detective and, eventually, sergeant. Although he never hid his name, many people were uncomfortable using it. To his police colleagues today, he is known as Lou. And what of his brother? The most noteworthy achievement of Winner Lane, now in his late 40s, is the sheer length of his criminal record: more than 30 arrests for burglary, domestic violence, trespassing, resisting arrest, and other mayhem. These days, Loser and Winner barely speak. The father who named them is no longer alive. Though he got his boys mixed up, did he have the right idea—is naming destiny? What kind of signal does a child's name send to the world?

These are the sort of questions that led to "The Causes and Consequences of Distinctively Black Names," a research paper written by a white economist (Steven Levitt, a co-author of this article) and a black economist (Roland G. Fryer Jr., a young Harvard scholar who studies race). The paper acknowledged the social and economic gulf between blacks and whites but paid particular attention to the gulf between black and white culture. Blacks and whites watch different TV shows, for instance; they smoke different cigarettes. And black parents give their children names that are starkly different than white children's. The names research was based on an extremely large and rich data set: birth-certificate information for every child born in California since 1961. The data covered more than 16 million births. It included standard items like name, gender, race, birthweight, and the parents' marital status, as well as more telling factors: the parents' ZIP code (which indicates socioeconomic status and a neighborhood's racial composition), their means of paying the hospital bill for the birth (again, an economic indicator), and their level of education.

The California data establish just how dissimilarly black and white parents have named their children over the past 25 years or so—a remnant, it seems, of the Black Power movement. The typical baby girl born in a black neighborhood in 1970 was given a name that was twice as common among blacks than whites. By 1980, she received a name that was 20 times more common among blacks. (Boys' names moved in the same direction but less aggressively—likely because parents of all races are less adventurous with boys' names than girls'.) Today, more than 40 percent of the black girls born in California in a given year receive a name that not *one* of the roughly 100,000 baby white girls received that year. Even more remarkably, nearly 30 percent of the black girls are given a name that is unique among every baby, white and black, born that year in California. (There were also 228 babies named Unique during the 1990s alone, and one each of Uneek, Uneque, and Uneqqee; virtually all of them were black.)

What kind of parent is most likely to give a child such a distinctively black name? The data offer a clear answer: an unmarried, low-income, undereducated, teenage mother from a black neighborhood who has a distinctively black name herself. Giving a child a super-black name would seem to be a black parent's signal of solidarity with her community—the flip side of the "acting white" phenomenon. White parents, meanwhile, often send as strong a signal in the opposite direction. More than 40 percent of the white babies are given names that are at least four times more common among whites.

So, what are the "whitest" names and the "blackest" names? Click [here](#) for the top 20 each for girls and [here](#) for the top 20 each for boys. (For the curious, we've also put together a list of the top 20 crossover names—the ones that blacks and whites are most likely to share.) And how much does your name really matter? Over the years, a series of studies have tried to measure how people perceive different names. Typically, a researcher would send two identical (and fake) résumés, one with a traditionally white name and the
other with an immigrant or minority-sounding name, to potential employers. The "white" résumés have always gleaned more job interviews. Such studies are tantalizing but severely limited, since they offer no real-world follow-up or analysis beyond the résumé stunt.

The California names data, however, afford a more robust opportunity. By subjecting this data to the economist's favorite magic trick—a statistical wonder known as regression analysis—it's possible to tease out the effect of any one factor (in this case, a person's first name) on her future education, income, and health.

The data show that, on average, a person with a distinctively black name—whether it is a woman named Imani or a man named DeShawn—does have a worse life outcome than a woman named Molly or a man named Jake. But it isn't the fault of his or her name. If two black boys, Jake Williams and DeShawn Williams, are born in the same neighborhood and into the same familial and economic circumstances, they would likely have similar life outcomes. But the kind of parents who name their son Jake don't tend to live in the same neighborhoods or share economic circumstances with the kind of parents who name their son DeShawn. And that's why, on average, a boy named Jake will tend to earn more money and get more education than a boy named DeShawn. DeShawn's name is an indicator—but not a cause—of his life path.

Regression analysis is a powerful—if limited—tool that uses statistical techniques to identify otherwise elusive correlations. Correlation is nothing more than a statistical term that indicates whether two variables move together. It tends to be cold outside when it snows; those two factors are positively correlated. Sunshine and rain, meanwhile, are negatively correlated. Easy enough—as long as there are only a couple of variables. But with a couple hundred variables, things get harder. Regression analysis is the tool that enables an economist to sort out these huge piles of data. It does so by artificially holding constant every variable except the two he wishes to focus on, and then showing how those two co-vary.

In the case of a complicated data set that concerns, for instance, the test scores of 20,000 schoolchildren, it might help to think of regression analysis as performing the following task: converting each of those schoolchildren into a sort of circuit board with an identical number of switches. Each switch represents a single category of the child's data: his first-grade math score, his third-grade math score, his first-grade reading score, his third-grade reading score, his mother's education level, his father's income, the number of books in his home, the relative affluence of his neighborhood, and so on. Now a researcher is able to tease some insights from this very complicated set of data. He can line up all the children who share many characteristics—all the circuit boards that have their switches flipped the same direction—and then pinpoint the single characteristic they don't share. This is how he isolates the true impact of that single switch on the sprawling circuit board. This is how the effect of that switch—and, eventually, of every switch—becomes manifest. She is a highly intelligent girl and this monologue is one of the most profound observations in all of Shakespeare. This principle of things being what they are, no matter what name you give them is at the heart of the tragedy of Romeo and Juliet. Whether you are called Montague or Capulet you are still the same person, and that's what matters. A rose by any other name quote in context. Juliet has met Romeo at her father's party and thinks he has gone home, but he is lingering in her garden, watching the balcony of her bedroom. She comes out and he overhears her speaking. Then that he shows himself to her and the action between them begins, leading to their secret marriage and their deaths. Freakonomics A Roshanda By Any Other Name 101 Summary: Chapter six of Freakonomics, kind of plays off of chapter five of what it takes to be a perfect parent. Therefore the beginning of chapter six starts off by saying the first official act of being a parent is giving the baby a name (Levitt and Dubner, 2009). In recent years the baby naming industry has skyrocketed. There are all kinds of baby naming books, websites, generators, etc… Parents have set in their mind that if they name their baby the wrong name they will be doomed for life. However, in a recent situation, Freakonomics Chapter 6: Perfect Parenting, Part II; or: Would a Roshanda by Any Other Name Smell as Sweet? | Summary. Share. Because names often are linked to cultures, different cultures have different connections to names. Economist Roland G. Fryer Jr. studied how separate black and white cultures are, finding that blacks and whites consume different media, smoke different cigarettes, and give their children very different names. Rather, the association with names reflects socioeconomic backgrounds and opportunities. Children with uniquely black names tend to come from less advantaged backgrounds. Obvious relationships between income and names exist even among the most common "white" names.
